ABSTRACT

The liquid crystal display of the present invention includes: a liquid crystal panel including vertical alignment liquid crystals encapsulated between a first substrate and a second substrate; a first compensation layer stacked on one side of the first layer; a first polarizing layer stacked on one side of the first compensation layer; a second compensation layer stacked on one side of the second substrate; and a second polarizing layer stacked on one side of the second compensation layer, wherein the first compensation layer includes a polyimide copolymer, and the polyimide copolymer is a copolymer of a monomer mixture including maleimide compounds and aromatic vinyl compounds. The liquid crystal display provides significantly improved lateral viewing angle.

LIQUID CRYSTAL DISPLAY

TECHNICAL FIELD

The present invention relates to a liquid crystal display, and more particularly, to a vertical alignment liquid crystal display that includes a compensation layer capable of improving a viewing angle.

BACKGROUND ART

Currently, liquid crystal displays (LCD) are one of the most widely used flat panel displays. In general, a liquid crystal display has a liquid crystal layer encapsulated between a thin film transistor array substrate and a color filter substrate. When an electric field is applied to electrodes on the array substrate and the color filter substrate, liquid crystal molecules of the liquid crystal layer encapsulated between the substrates are rearranged, thereby displaying an image. The liquid crystal display includes a polarizing film (polarizing plate) outside the array substrate and the color filter substrate. The polarizing film can control polarization of light by allowing selective transmission of light traveling in a certain direction among light emitted from a backlight unit and having passed through the liquid crystal layer. The polarizing plate generally includes a polarizer capable of polarizing light in a certain direction, a protective layer, and a compensation film.

Liquid crystal displays have a fundamental problem of a viewing angle due to anisotropy of an index of refraction of liquid crystals. To improve the viewing angle of existing twisted nematic mode, wide viewing angle technologies such as vertical alignment mode, horizontal alignment mode (IPS, FFS) and the like have been employed.

Horizontal alignment mode liquid crystals have a disadvantage of slow response rate but provide a good contrast ratio and a good viewing angle at tilt angles. On the contrary, vertical alignment mode liquid crystals provide a rapid response rate and an excellent front contrast ratio. However, the vertical alignment mode liquid crystals exhibit low viewing angle characteristics due to severe fluctuation of a polarized state at tilt angles. Therefore, it is very important for liquid crystal displays employing the vertical alignment mode liquid crystals to improve the viewing angle characteristics, and a compensation film for improving the viewing angle is essential for the liquid crystal displays employing the vertical alignment mode liquid crystals.

In conventional liquid crystal displays employing the vertical alignment mode liquid crystals, the slow axis is managed by biaxial elongation. However, when the slow axis is managed by biaxial elongation, the slow axis must be set in a width direction, which necessitates separate elongation in a transverse direction, thereby making it difficult to manage the axis and increasing manufacturing costs.

DISCLOSURE

Technical Problem

An object of the present invention is to provide a liquid crystal display which can significantly improve viewing angle (contrast ratio).

Another object of the present invention is to provide a liquid crystal display including a uniaxially oriented compensation layer, which can facilitate axis management, and reduce costs.

2

Still another object of the present invention is to provide a vertical alignment liquid crystal display which provides a greatly improved lateral viewing angle (contrast ratio).

Technical Solution

One aspect of the present invention provides a liquid crystal display. The liquid crystal display includes: a liquid crystal panel including vertical alignment liquid crystals encapsulated between a first substrate and a second substrate; a first compensation layer stacked on one side of the first layer; a first polarizing layer stacked on one side of the first compensation layer; a second compensation layer stacked on one side of the second substrate; and a second polarizing layer stacked on one side of the second compensation layer, wherein the first compensation layer comprises polyimide copolymer. Here, the polyimide copolymer is a copolymer of a monomer mixture including maleimide compounds and aromatic vinyl compounds.

In one embodiment, the monomer mixture may further include maleic anhydride.

In one embodiment, the monomer mixture may further include maleic anhydride and a vinyl cyanide compound.

In one embodiment, the polyimide copolymer may include a unit represented by Formula 1-1, a unit represented by Formula 1-2, a unit represented by Formula 1-3, and a unit represented by Formula 1-4:

[Formula 1-1]

[Formula 1-2]

[Formula 1-3]

[Formula 1-4]

in the Formula 1-1, R is hydrogen, a substituted or unsubstituted $\text{C}_1\text{-C}_6$ alkyl group, or a substituted or unsubstituted $\text{C}_6\text{-C}_{12}$ aryl group; and

in the Formula 1-2, Ar is each independently a substituted or unsubstituted $\text{C}_1\text{-C}_{12}$ aryl group.

In one embodiment, the polyimide copolymer may be represented by Formula 1:

[Formula 1]

in the Formula 1, R is hydrogen, a substituted or unsubstituted $\text{C}_1\text{-C}_6$ alkyl group, or a substituted or unsubstituted $\text{C}_6\text{-C}_{12}$ aryl group; Ar is each independently a substituted or

3

unsubstituted C_1 - C_{12} aryl group; and M and N are each independently an integer from 2 to 8.

In one embodiment, the first compensation layer may have reversed wavelength dispersion characteristics.

In one embodiment, the first compensation layer may have C_s of about -0.7 to about -0.2 , R_e of about 40 nm to about 100 nm at about 550 nm, and R_{th} of about 100 nm to about 150 nm at about 550 nm.

In one embodiment, the second compensation layer may be a biaxial film or a C-plate.

In one embodiment, the biaxial film may have indexes of refraction (n_x , n_y) in x and y directions on a plane and an index of refraction (n_z) in a thickness direction satisfying a relationship: $n_x > n_y > n_z$, R_e of greater than 0 ($R_e > 0$), and R_{th} of less than 0 ($R_{th} < 0$). The biaxial film may be a cycloolefin polymer (COP), triacetylcellulose (TAC), or polyether sulfone (PES) compensation film.

In one embodiment, the C-plate may be a COP or acrylic compensation film having indexes of refraction (n_x , n_y) in x and y directions on a plane and an index of refraction (n_z) in a thickness direction satisfying a relationship: $n_x = n_y < n_z$, and R_{th} of greater than 0 ($R_{th} > 0$).

In one embodiment, the first compensation layer may have a slow axis perpendicular to a slow axis of the second compensation layer. Here, the slow axis of the first compensation layer may be perpendicular to an absorption axis of the first polarizing layer, and the slow axis of the second compensation layer may be perpendicular to the absorption axis of the second polarizing layer.

Advantageous Effects

The present invention has the inventive effect providing a liquid crystal display including a uniaxially oriented compensation layer, which can significantly improve viewing angle (contrast ratio), facilitate axis management, and reduce costs, and more particularly, a vertical alignment liquid crystal display which provides a greatly improved lateral viewing angle (contrast ratio).

DESCRIPTION OF DRAWINGS

FIG. 1 is a cross sectional view of a liquid crystal display according to one embodiment of the present invention.

FIG. 2 is a conceptual view explaining an optical axis of a liquid crystal display according to one embodiment of the present invention.

FIGS. 3 and 4 show simulation results of contrast ratio at every longitude angle of vertical alignment mode liquid crystal display of Examples 1 and 2 simulated using white light.

BEST MODE

Hereinafter, embodiments of the present invention will be described in detail with reference to the accompanying drawings.

FIG. 1 is a cross sectional view of a liquid crystal display according to one embodiment of the present invention. In FIG. 1, the liquid crystal display 100 according to one embodiment of the present invention includes a liquid crystal panel including a liquid crystal layer 102 encapsulated between a first substrate 104 and a second substrate 106, wherein a first optical film 110 is stacked on one side (upper side) of the first substrate 104 and a second optical film 120 is stacked on one side (lower side) of the second substrate 106.

4

As used herein, the terms "upper side" and "lower side" are named for convenience with reference to upper and lower sides of the drawings and do not necessarily refer to an upper part and a lower part.

In one embodiment, the first substrate 104 may be a color filter (CF) substrate (upper substrate) and the second substrate 106 may be a thin film transistor (TFT) substrate (lower substrate).

The first substrate 104 and the second substrate 106 may be glass substrates or plastic substrates. The plastic substrate is applicable to flexible displays and may be comprised of at least one polymer selected from the group consisting of polyethylene terephthalate (PET), polycarbonate (PC), polyimide (PI), polyethylene naphthalate (PEN), polyether sulfone (PES), polyarylate (PAR), and cycloolefin copolymers (COC), without being limited thereto.

The first optical film 110 of the present invention may include a first compensation layer 112 and a first polarizing layer 114. The first optical film 110 may further include a first protective layer 116, and the like. Namely, the first optical film 110 may be a polarizing plate including a polarizing layer (polarizer).

The first compensation layer 112 may be comprised of a polyimide (PI) copolymer. The polyimide copolymer may be a copolymer of a monomer mixture, which include a maleimide compound and an aromatic vinyl compound. For example, the monomer mixture may further include maleic anhydride. Preferably, the monomer mixture further includes maleic anhydride and a vinyl cyanide compound.

In other words, the copolymer of the first compensation layer 112 may include a repeat unit of Formula 1-1 derived from a maleimide compound (N-substituted maleimide):

wherein R is hydrogen, a substituted or unsubstituted C_1 - C_6 alkyl group, or a substituted or unsubstituted C_6 - C_{12} aryl group; and a repeat unit of Formula 1-2 derived from an aromatic vinyl compound:

wherein Ar is a substituted or unsubstituted C_6 - C_{12} aryl group, and optionally include a repeat unit of Formula 1-3 derived from maleic anhydride:

and a repeat unit of Formula 1-4 derived from a vinyl cyanide compound:

−0.7 to about −0.2, which enables manufacture of a compensation layer (film) having C_s values in a wider range.

The first compensation layer **112** may be formed in a film shape and stacked with the first polarizing layer **114**. The first compensation layer may have a thickness in the range from about 5 μm to about 100 μm . The thickness of the compensation layer can be suitably adjusted depending on the kind of liquid crystal (physical properties), the thickness of the liquid crystal layer, and the like.

The first polarizing layer **114** may include a polarizer prepared by dyeing a polyvinyl alcohol (PVA) film with a dichromatic material such as iodine, followed by stretching the film. The polyvinyl alcohol film can be commercially available or prepared by solvent casting, melt extrusion, and the like. In solvent casting, a film may be prepared by dissolving a resin in a solvent to form a solution, coating the resultant solution onto a casting roll or a belt, and drying the coating. In melt extrusion, a film may be prepared by heating a resin to a melting temperature to melt the resin, extruding the melt in a cold roll, and cooling the melt.

The solution to prepare the film may further include a plasticizer to enhance flexibility of the polyvinyl alcohol film, and a surfactant to release the dried polyvinyl alcohol film from a belt or a drum. The polyvinyl alcohol film prepared as such or conventional polyvinyl alcohol film may be stretched to prepare a polarizer (polarizing layer). In detail, the polyvinyl alcohol may be subjected to washing/swelling, dyeing, crosslinking, stretching, and complementary color treatment.

The polarizer includes a long chain ring of hydrocarbons arranged in a row in the stretching direction of the polyvinyl alcohol film. The chain ring has conductivity owing to the iodine molecules dyed thereto. Since light having an electric field vector parallel to the chain ring can be absorbed, the stretching direction becomes a light absorption axis, while the axis perpendicular to the absorption axis is referred to as a transmission axis.

The first protective layer **116** may be comprised of, for example, acetates such as triacetylcellulose (TAC), polycarbonates, polyamides, polyimides, polyolefins, polyesters, polyethersulfone, and polypropylene (PP) films. Preferably, a TAC film is used.

Further, a pressure sensitive adhesive may be formed under the first compensation layer **112**, namely, between the first substrate **104** and the first compensation layer **112**. A surface treatment layer (not shown) may be formed on one side (upper side) of the first protective layer **116**. The surface treating layer may be an antiglare layer (AG) or an anti-reflection coating (ARC) layer.

The second optical film **120** of the present invention may include a second compensation layer **122** and a second polarizing layer **124**. In addition, the second optical film **120** may include a second protective layer **126**. The second polarizing layer **124** is the same as the first polarizing layer **114** and may be a polarizer (polarizing layer) manufactured by the same method, provided that the second polarizing layer **124** and the first polarizing layer **114** may be cut in the cutting process such that the optical axes (absorption axis) of the polarizers are perpendicular (90°) to each other.

The second compensation layer **122** may be a biaxial film or a C-plate. The biaxial film may be a positive biaxial film in which the index of refraction in the x and y directions (n_x , n_y) on a plane and the index of refraction in the thickness direction (n_z) satisfy the relationship $n_x > n_y > n_z$. Preferably, the second compensation layer is a cycloolefin polymer (COP) film, triacetylcellulose (TAC) film, or a polyether sulfone (PES) film.

The C-plate may be a positive C-plate in which the refractive indices n_x and n_y in the x and y direction on a plane and the index of refraction n_z in a thickness direction satisfy the relationships $n_x = n_y < n_z$ and $R_{th} > 0$. The C-plate may be made of homeotropic liquid crystals and may be a COP or an acrylic C-plate.

The liquid crystal layer **102** may be a liquid crystal layer including vertical alignment (VA) mode liquid crystals. Examples of the vertical alignment mode include multi-domain vertical alignment mode in which a ridge including electrode pairs on the first substrate and second substrate is formed on a surface adjacent the liquid crystal layer to form a multi-domain, patterned vertical alignment mode in which a multi-domain structure is formed by applying voltage to patterned electrodes, vertical alignment mode using chiral additives and the like, wherein the cell gap of the liquid crystal cell may be about 2 to about 8 μm .

FIG. 2 is a conceptual view explaining an optical axis of the liquid crystal display according to one embodiment of the present invention. As shown in FIG. 2, the slow axis **112a** of the first compensation layer **112** may be perpendicular to the absorption axis **114a** of the first polarizing layer; the slow axis **112a** of the first compensation layer may be perpendicular to the slow axis **122a** of the second compensation layer **122**; and the slow axis **122a** of the second compensation layer **122** may be perpendicular to the absorption axis **124a** of the second polarizing layer **124**. When arranged as mentioned above, the two phase retardation films exhibit excellent wavelength dispersion characteristics such as a good index of refraction, thereby significantly improving viewing angle characteristics. Particularly, the lateral viewing angle (contrast ratio) is remarkably improved.

The term “perpendicular” as used in description of the optical axis arrangement means that it includes the case where the optical axis is arranged substantially perpendicular to another axis. For example, the absorption axis **114a** of the first polarizing layer **114** is perpendicular to the absorption axis **124a** of the second polarizing layer **124**, wherein the perpendicular degree includes about $90^\circ \pm \text{about } 2.0^\circ$, preferably about $90^\circ \pm \text{about } 1.0^\circ$, more preferably about $90^\circ \pm \text{about } 0.5^\circ$.

The liquid crystal display has a slow axis and a rapid axis perpendicular to a traveling direction of light and these two axes are perpendicular to each other. The first compensation layer **112** and the second compensation layer **122** serve to change phase velocity of incident light such that the velocity of polarized light traveling along the slow axis becomes slower.

Mode for Invention

Next, the present invention will be explained in more detail with reference to some examples. These examples are provided for illustration only and are not to be construed in any way as limiting the present invention.

EXAMPLE

Examples 1~7

A color filter substrate was used as an upper substrate, that is, a first substrate. As a first compensation layer, a PI compensation film was attached to the first substrate. A first polarizing layer and a first protective layer were stacked in this order to one side of the first compensation layer. A TFT substrate was used as a lower substrate, that is, a second

substrate. As a second compensation layer, a biaxial or C-plate compensation film was attached to one side of the second substrate. In addition, a second polarizing layer and a second protective layer were stacked in this order to one side of the second compensation layer, thereby manufacturing a vertical alignment mode liquid crystal display. The first compensation layer and the second compensation layer are as listed in Table 1.

Comparative Examples 1~4

The vertical alignment mode liquid crystal display was manufactured in the same manner as in Example 1 except that the first compensation layer and the second compensation layer were changed as listed in Table 1.

TABLE 1

	Upper substrate (CF surface)		Lower substrate (TFT surface)	
	Cs	Compensation film	Cs	Compensation film
Example 1	-0.23	PI	-0.5	Biaxial
Example 2	-0.58	PI	-0.01	C-plate
Example 3	-0.23	PI	-0.3	Biaxial
Example 4	-0.58	PI	-0.5	Biaxial
Example 5	-0.58	PI	-0.3	Biaxial
Example 6	-0.58	PI	-0.05	C-plate
Example 7	-0.23	PI	-0.05	C-plate
Comparative Example 1	-0.5	Biaxial	-0.5	Biaxial
Comparative Example 2	-0.3	Biaxial	-0.3	Biaxial
Comparative Example 3	-3.2	A-plate	-0.01	C-plate
Comparative Example 4	-3.2	A-plate	-0.05	C-plate

*PI compensation film: The PI compensation film includes a copolymer represented by Formula 1, and has indexes of refraction n_x and n_y in the x and y directions on a plane and an index of refraction n_z in the thickness direction satisfying the relationships $n_x > n_y > n_z$, R_x of 40 nm to 100 nm, and R_y of 100 nm to 150 nm. The PI compensation film used in Examples 1, 3 and 7 were compensation films satisfying $R_x/R_y = 50/135$ nm at 550 nm. The PI compensation film used in Examples 2, 4 to 6 were compensation films satisfying $R_x/R_y = 40/125$ nm at 550 nm.

*Biaxial compensation film: The biaxial film (Zeon Inc.) having indexes of refraction n_x and n_y in the x and y directions on a plane and an index of refraction n_z in a thickness direction satisfying a relationship: $n_x > n_y > n_z$, $R_x > 0$, and $R_y < 0$ was used.

*C-plate compensation film: The compensation film (JSR Inc.) having indexes of refraction n_x , n_y in the x and y directions on a plane and an index of refraction (n_z) in the thickness direction satisfying a relationship: $n_x = n_y < n_z$, and $R_y > 0$ was used.

*A-plate compensation film: The compensation film (JSR Inc.) having indexes of refraction n_x , n_y in the x and y directions on a plane and an index of refraction n_z in the thickness direction satisfying a relationship: $n_x > n_y = n_z$, and $R_x > 0$ was used.

Evaluation of Optical Properties

The compensation films of Examples 1~7 and Comparative Examples 1~4 shown in Table 1 were attached to vertical alignment mode liquid crystal panels and evaluated as to their optical properties. White and black brightness were measured using an SR3 apparatus. In addition, the lateral contrast ratio was calculated from white/black brightness at an azimuth angle (Φ) of 45° and a polar angle (θ) of 60°. Results are summarized in Table 2.

FIGS. 3 and 4 show simulation results of contrast ratio at every coterminal angle of vertical alignment mode liquid crystal displays of Examples 1 and 2 simulated using white light.

TABLE 2

	White Brightness (unit: cd)	Black Brightness (unit: cd)	Lateral contrast ratio
Example 1	58	0.38	153
Example 2	58	0.41	141
Example 3	57	0.42	136

TABLE 2-continued

	White Brightness (unit: cd)	Black Brightness (unit: cd)	Lateral contrast ratio
Example 4	58	0.43	135
Example 5	53	0.40	133
Example 6	56	0.43	131
Example 7	51	0.38	134
Comparative Example 1	57	0.71	80
Comparative Example 2	54	0.70	77
Comparative Example 3	57	0.52	110
Comparative Example 4	51	0.50	102

As apparent from Table 2, it can be seen that the average lateral contrast ratio of the liquid crystal displays in Examples 1 to 7 was 137.4 and the average lateral contrast ratio of the liquid crystal displays in Comparative Examples 1 to 4 was 92.3, that is, average lateral contrast ratio of the liquid crystal displays of Examples 1 to 7 was about 49% higher than that of the liquid crystal displays in Comparative Examples 1 to 4.

Although some embodiments have been disclosed herein, it should be understood by those skilled in the art that these embodiments are provided by way of illustration only, and that various modifications, changes, and alterations can be made without departing from the spirit and scope of the present invention. Therefore, the scope of the present invention should be limited only by the accompanying claims and equivalents thereof.

The invention claimed is:

1. A liquid crystal display, comprising:

a liquid crystal panel including vertical alignment liquid crystals encapsulated between a first substrate and a second substrate;

a first compensation layer stacked on one side of the first substrate;

a first polarizing layer stacked on one side of the first compensation layer;

a second compensation layer stacked on one side of the second substrate; and

a second polarizing layer stacked on one side of the second compensation layer,

wherein the first compensation layer includes a polyimide copolymer, the polyimide copolymer being a copolymer of:

a first copolymer including repeating units of a maleimide compound and an aromatic vinyl compound, and a second copolymer including repeating units of an aromatic vinyl compound and a vinyl cyanide compound.

2. The liquid crystal display according to claim 1, wherein the first copolymer further includes repeating units of maleic anhydride.

3. The liquid crystal display according to claim 2, wherein the polyimide copolymer includes a unit represented by Formula 1-1, a unit represented by Formula 1-2, a unit represented by Formula 1-3, and a unit represented by Formula 1-4:

[Formula 1-1]

11

-continued

[Formula 1-2]

[Formula 1-3]

[Formula 1-4]

in the Formula 1-1, each R is independently hydrogen, a substituted or unsubstituted C₁-C₆ alkyl group, or a substituted or unsubstituted C₆-C₁₂ aryl group; and in the Formula 1-2, each Ar is independently a substituted or unsubstituted C₆-C₁₂ aryl group.

4. The liquid crystal display according to claim 2, wherein the polyimide copolymer is represented by Formula 1:

[Formula 1]

in the Formula 1, each R is independently, a substituted or unsubstituted C₁-C₆ alkyl group, or a substituted or unsubstituted C₆-C₁₂ aryl group; each Ar is independently a substituted or unsubstituted C₆-C₁₂ aryl group; and M and N are each independently an integer from 2 to 8.

5. The liquid crystal display according to claim 1, wherein the first compensation layer has reversed wavelength dispersion characteristics.

6. The liquid crystal display according to claim 1, wherein the first compensation layer has C_s of about -0.7 to about -0.2.

7. The liquid crystal display according to claim 1, wherein R_e of the first compensation layer ranges from about 40 nm to about 100 nm at 550 nm.

8. The liquid crystal display according to claim 1, wherein R_{th} of the first compensation layer ranges from about 100 nm to about 150 nm at 550 nm.

9. The liquid crystal display according to claim 1, wherein the second compensation layer is a biaxial film or a C-plate.

10. The liquid crystal display according to claim 9, wherein the biaxial film has indexes of refraction (n_x, n_y) in x and y directions on a plane and an index of refraction (n_z) in a thickness direction satisfying a relationship: n_x>n_y>n_z, R_e of greater than 0 (R_e>0), and R_{th} of less than 0 (R_{th}<0).

12

11. The liquid crystal display according to claim 9, wherein the biaxial film is a cycloolefin polymer (COP), triacetylcellulose (TAC), or polyether sulfone (PES) compensation film.

12. The liquid crystal display according to claim 9, wherein the C-plate is a cycloolefin polymer (COP) or acrylic compensation film having indexes of refraction (n_x, n_y) in x and y directions on a plane and an index of refraction (n_z) in a thickness direction satisfying a relationship: n_x=n_y<n_z, and R_{th} of greater than 0 (R_{th}>0).

13. The liquid crystal display according to claim 1, wherein the first compensation layer has a slow axis perpendicular to a slow axis of the second compensation layer, the slow axis of the first compensation layer being perpendicular to an absorption axis of the first polarizing layer, the slow axis of the second compensation layer being perpendicular to the absorption axis of the second polarizing layer.

14. A compensation film comprising a copolymer of:

a first copolymer of a maleimide compound, an aromatic vinyl compound, and maleic anhydride, and

a second copolymer of a vinyl cyanide compound and an aromatic vinyl compound.

15. The compensation film according to claim 14, wherein the compensation film has C_s of -0.7 to -0.2, R_e of about 40 nm to about 100 nm at 550 nm, and R_{th} of about 100 nm to about 150 nm at 550 nm.

16. A liquid crystal display, comprising:

a liquid crystal panel that includes vertical alignment liquid crystals encapsulated between a first substrate and a second substrate;

a first compensation layer stacked on one side of the first substrate;

a first polarizing layer stacked on one side of the first compensation layer;

a second compensation layer stacked on one side of the second substrate; and

a second polarizing layer stacked on one side of the second compensation layer,

wherein the first compensation layer includes a polyimide copolymer represented by Formula 1:

[Formula 1]

wherein, in Formula 1,

each R is independently a substituted or unsubstituted C₁-C₆ alkyl group or a substituted or unsubstituted C₆-C₁₂ aryl group;

each Ar is independently a substituted or unsubstituted C₆-C₁₂ aryl group; and

M and N are each independently an integer from 2 to 8.
